

Cybersecurity Incident Report:

Network Traffic Analysis

Part 1: Provide a summary of the problem found in the DNS and ICMP traffic log.

Network protocol analyzer logs indicate that port 53 is inaccessible when accessing a company's website. Port 53 is the standard network port used by the Domain Name System (DNS). It is typically used to resolve human-readable website names into machine-readable IP addresses. This error may indicate issues with the DNS server or firewall configurations, or that the port is already in use.

Part 2: Explain your analysis of the data and provide at least one cause of the incident.

The incident occurred earlier today when clients reported being unable to access the company's website, www.yummyrecipesforme.com, encountering a "Destination Port Unreachable" error after waiting for the page to load. The cybersecurity team intervened immediately and began testing using the network protocol analysis tool tcpdump. The resulting logs indicated that port 53, used for the DNS server, was unreachable. We are continuing to investigate the root cause to determine how to restore access to the secure web portal. Next steps include checking firewall configurations to confirm whether port 53 is blocked and contacting the DNS server administrator to look for signs of a potential attack.
